Calling a routine repair an emergency costs a phone call.

Calling an emergency routine costs a flooded unit.

Those two numbers aren't close.

Most processes treat the two mistakes as if they were the same size.

Nobody priced them.

It isn’t ~~a judgment failure~~. It’s an arithmetic one that never happened.

So the rule writes itself:

every ambiguous case resolves upward, before anyone has a chance to be optimistic.

In my build, fixed rules run after the model.

They can raise a priority. There is no code path to ~~lower one~~.

This over-escalates. A manager sometimes gets an alert for something that could have waited.

That’s the cheaper mistake.

Find one judgment call in your business where the two errors cost wildly different amounts.

Check whether your process knows.
